

JAPANESE WHALE HUNTERS

Detection & Position Management Rubric

A Forensic Framework for Identifying Institutional Narrative Positioning

CORE PRINCIPLE

Whales positioning to narrate markets are not just moving money — they are running an information distortion infrastructure. That infrastructure has consistent structural fingerprints regardless of the asset, sector, or actor. This rubric provides a systematic, phase-gated methodology for detecting the infrastructure, identifying the actor, timing the move, sizing the position, and managing exit.

DETECTION SEQUENCE DISCIPLINE

Each phase narrows the field and compounds confidence. The rubric only reaches full actionability when all phases compound. Never skip phases to accelerate entry — skipping phases is how you become exit liquidity.

Signal Hierarchy

Phase 1 operates on three entry signals. Signal weight is not equal — the hierarchy below governs confidence weighting and position sizing ceilings.

PRIMARY MANAGED SILENCE

The structurally absent story. Not missing by accident but missing consistently across multiple outlets simultaneously. The coherence of the silence is the tell — random omission is ragged, managed omission has a clean edge. Requires sustained multi-party coordination over time. Most expensive information management operation and therefore most intentional.

SECONDARY COERCION DISPLACEMENT

Visible culpability held disproportionately by small actors while institutional architecture stays unnamed above them. Deliberate, but may be institutionally habituated rather than actively managed in real time. When the 'who's responsible' answer keeps landing on the least powerful node, that's manufactured.

**TERTIARY
CONSENSUS
REDUNDAN
CY**

Same framing, same language, suspiciously similar timing across nominally independent sources. Organic agreement is textured and arrives staggered. Coordinated agreement is flat and arrives in clusters. Can be semi-emergent in captured media ecosystems — does not alone confirm active whale positioning. Caps position size at Tier 1 if unaccompanied by Managed Silence.

CRITICAL: When Managed Silence is absent and only Consensus Redundancy is present, confidence ceiling drops significantly. You may be reading a captured ecosystem, not active positioning.

PHASE

1

Narrative Anomaly Detection

Is information management occurring at all?

A. Managed Silence (Primary Signal)

Identify what is structurally absent. Map the shape of the silence across outlets. Ask: is the same angle, the same counterparty perspective, the same set of facts missing from multiple independent sources? Cross-check the silence against what would naturally be present if the story were organically developing. Managed silence has a clean edge — it cuts off at the same point regardless of the outlet carrying it.

B. Coercion Displacement (Secondary Signal)

Locate where visible culpability is landing. When small actors consistently hold disproportionate blame while the institutional architecture above them stays unnamed, the naming structure itself is the manufactured product. The eye-level reality of the implicated person is not an accurate read of the situation — it is the output of active information management. Coercion displacement is both a detection signal and a fingerprint for the actor running the infrastructure.

C. Consensus Redundancy (Tertiary Signal)

Track framing consistency and timing across nominally independent sources. Redundancy that is too flat, too synchronized, or too linguistically similar signals coordination. Organic agreement has texture — it arrives staggered, uses varied language, reflects independent analysis. Coordinated agreement is smooth and arrives in clusters. Note which PR architecture, analyst relationships, and media fingerprints appear across the redundant coverage.

Phase 1 Diagnostic Question: *Is the information structure too clean?*

Single signal opens investigation. Managed Silence preferred. Consensus Redundancy alone = watch only, Tier 1 ceiling.

PHASE
2

Actor Identification

Who has motive and means to run this infrastructure?

Inversion Test

Run the narrative from the counterparty's position. Ask: does this story cohere from the other side? If it only coheres from one direction, the selection of what is managed reveals whose interests it serves. This identifies the actor with motive. The inversion test is also a validity check — legitimate information environments survive inversion; managed ones collapse when run backwards.

Maintenance Infrastructure Trace

Managed narratives share vendors: PR architecture, media relationships, analyst relationships, think-tank citations. These get recycled across institutional actors. Map the fingerprint — same framing appearing in which publications, same analysts upgrading or downgrading, same third-party voices cited across the coverage. The infrastructure itself is named and traceable even when its client is not. Document this fingerprint in the Infrastructure Recycling Log for future cycle detection.

Diffusion Alibi Inventory

List all the partial alibis in play simultaneously. Each individual node — the analyst, the regulator, the journalist, the earnings call — appears locally legitimate. But when multiple partial alibis are simultaneously available, intentionality is implied. Alibis presuppose someone needed one. The density of simultaneous partial alibis is proportional to the scale of the positioning.

Diffusion Alibi Mechanics:

- Causal weight distributed across locally-legitimate nodes produces global exculpation no single node could generate alone
- Partial alibis aggregate into a total alibi — no single actor looks culpable
- Intentionality is preserved in the pattern even when absent from each node individually
- Applicable to: institutional post-mortems, earnings calls, apologies, industry narratives, regulatory filings

Phase 2 Diagnostic Question: *Who benefits from this specific selection of managed content?*

Phase 2 confirmation required before Tier 2 position build. If actor identification is ambiguous, hold at Tier 1.

Temporal Mapping

Where are we in the lifecycle, and how fast is it moving?

Lag Gap Velocity

Measure the gap between the maintained narrative and underlying reality, then track the rate of change of that gap. Slow widening indicates early accumulation — patient positioning, time remains. Accelerating gap indicates distribution approaching and exit timeline compressing. If the gap begins narrowing — fundamentals catching up to narrative, or narrative retreating toward fundamentals — the maintenance infrastructure is being wound down. That is pre-exit behavior.

Interior Bubble Profile

Analyze the distribution of trapped positions within the node. A peaked, narrow interior bubble means trapped positions are highly synchronized — when the node boundary breaks, exit behavior becomes nearly simultaneous rather than staggered. This predicts velocity and acceleration of the move, not just direction. Institutional accumulation within a node happens in tranches, producing a stepped or layered interior profile. Retail bubbles trend toward smoother distributions because retail entries are emotionally triggered and more randomly timed. The shape asymmetry tells you who owns the position — and therefore how exit will behave.

Incomplete Distribution Signal

If prior node analysis shows the actor only partially distributed before price moved, a re-entry is predictable. They will return to complete the position. Do not treat a broken node as closed — treat it as interrupted. Log the node boundary in the Infrastructure Recycling Log for re-entry watch.

FLAT / DISTRIBUTED

Slow bleed. Retail or distributed accumulation. Lower velocity exit.

PEAKED / NARROW

Synchronized positions. Near-simultaneous exit when node breaks. High velocity.

STEPPED / LAYERED

Institutional tranches. Whale signature. Predictable re-entry if incomplete.

Phase 3 Diagnostic Question: *Where are we in the lifecycle, and how fast is it moving?*

Temporal confirmation required before Tier 3 full position. Phase 3 compresses fast — Tier 3 executes in one move, not averaged.

PHASE
4

Actionability & False Positive Filter

High-confidence read vs. noise?

Compounding Threshold

Phase 1 only (Managed Silence)	Elevated watch. Open investigation.
Phase 1 only (Consensus Redundancy)	Watch only. Tier 1 ceiling. Do not build.
Phase 1 + Phase 2 confirmed	Thesis is real. Build to Tier 2.
Phase 1 + Phase 2 ambiguous	Hold at Tier 1. Do not build until resolved.
All three phases compounded	Full conviction. Execute Tier 3. Activate Stage B.

False Positive Discrimination

The key discriminator: organic patterns are ragged and distributed; managed patterns are clean and synchronized. When something looks too coherent across too many independent nodes simultaneously, that coherence is the artifact.

What looks like whale positioning but is not:

- Genuine bad news with organic silence — no managed consensus redundancy accompanying it
- Sector-wide sentiment shift — no single actor traceable in the infrastructure fingerprint
- Retail momentum — interior bubble shows smooth distribution, not stepped institutional tranches

Position-Sizing Module

Size is a function of compounded signal confidence — not conviction feeling. The rubric removes emotion from sizing by making allocation mechanical. The loudest, most obvious signal (Consensus Redundancy) receives the smallest allocation. The quietest, most expensive-to-produce signal (Managed Silence) receives the largest. You are betting against the noise and with the silence — the direct inversion of what the whale's exit liquidity pool does.

TIER 1 PROBE 10–15% of intended full position

TRIGGER: Single Phase 1 signal only. Managed Silence preferred. Consensus Redundancy alone caps at 10% ceiling.

- No averaging up until Phase 2 actor is confirmed
- Hard stop if triggering Phase 1 signal reverses before Phase 2 fires

- Run parallel paper-trade thesis simultaneously to track signal accuracy without capital risk on unconfirmed portion

TIER 2 CORE BUILD 40–50% of total position

TRIGGER: Phase 1 primary signal (Managed Silence) confirmed + Phase 2 actor identification holds. Inversion test run and narrative fails to cohere from counterparty position.

- Add to Tier 1 probe — do not replace it. Average entry improves.
- Diffusion Alibi inventory must be completed before this tier executes
- If actor identification diffuses (cannot pin infrastructure to single node cluster), hold at Tier 1

TIER 3 FULL POSITION Remaining 35–50% — one move, not averaged

TRIGGER: All three phases compounded. Phase 3 temporal signals firing — lag gap accelerating, interior profile peaked/narrow, lifecycle placement confirmed in accumulation-to-pump transition.

- Execute in one move — by the time Phase 3 compresses, there is no time to ladder in slowly
- Simultaneously activate Stage B position monitoring from the moment Tier 3 deploys
- Stop loss structure shifts from signal-based to price-based at this tier — price action is the cleanest real-time signal

Sizing Override Conditions

FORCED DOWNGRADE (drop one tier)

- Phase 2 actor identification ambiguous — infrastructure fingerprint matches two or more unrelated node clusters
- Interior profile shows smooth distribution, not stepped institutional tranches — you may be entering retail momentum
- Thesis Integrity Check reveals entry was primarily Consensus Redundancy without Managed Silence — cap at Tier 1 permanently for this trade

FORCED UPGRADE (compress Tier 1+2)

- Infrastructure Recycling Log confirms this actor has run this exact playbook before
- Prior cycle is fully documented — known actor, known infrastructure, known lifecycle timing
- Pattern recognition across trades compresses the confirmation window — enter larger, faster

Parallel Track: Position Management

When you are outside a position, you are reading narrative construction. When you are inside, you are reading narrative decay. The same signals that confirm entry, in reverse and in deterioration, confirm exit. The rubric is symmetric — which is also how you know it is structurally sound rather than retrofitted.

Stage A — Thesis Integrity Check

Before monitoring decay, confirm you entered on a real signal.

- Retroactively run Phase 1–3 against your entry thesis. Which signal triggered entry?
- If entry was primarily Consensus Redundancy without Managed Silence confirmed: re-evaluate position size. You may be riding momentum, not whale positioning — different risk profile, different exit logic.
- Has Phase 2 actor identification held? Is the infrastructure still traceable to the same node cluster, or has it diffused? Diffusion post-entry suggests the original actor may already be distributing while new, smaller actors amplify the narrative. Yellow flag.

Stage B — Active Position Monitoring

Watch for narrative maintenance integrity, lag gap behavior, and interior profile shifts simultaneously.

Maintenance Integrity Signals

- New voices entering the consensus that do not share the same infrastructure fingerprint — organic agreement mixing with managed agreement signals the narrative is going viral beyond the whale's control, meaning distribution is near
- Partial alibis beginning to contradict each other at the edges — Diffusion Alibi structure showing stress
- Previously silent angles receiving any mainstream coverage — managed silence breaking is the loudest possible exit signal

Lag Gap Behavior

- While in position, gap should be stable or still widening in your favor
- If the gap begins narrowing — fundamentals catching up to narrative, or narrative retreating toward fundamentals — maintenance infrastructure is being wound down. Pre-exit behavior.

Interior Profile Shift

- Stepped/layered institutional accumulation signature transitioning to smoother distribution curve signals whale handing off to exit liquidity pool
- Retail volume increasing while institutional tranches stop appearing — be out before you become the exit liquidity

Stage C — Exit Signal Cascade

Signals ordered by urgency. Do not wait for Red before acting on Yellow.

YELLOW cale Back

- Consensus Redundancy peaks and flattens — narrative saturation, no new converts to manufacture
- One previously managed silence breaks in a secondary outlet
- Lag gap velocity reverses direction even slightly
- Interior profile beginning to flatten — retail takeover initiating

ORANGE ccelerate

- Managed Silence breaks in a primary outlet
- Diffusion Alibi nodes begin issuing hedged or contradictory statements — partial alibis retracting
- Coercion Displacement actors start getting named — institutional architecture above them being exposed, maintenance infrastructure being abandoned
- Actor identified in Phase 2 shows fingerprint in a different narrative simultaneously — repositioning, not maintaining

RED Full Exit

- The inversion test flips — narrative now coheres from the counterparty's position
- Managed Silence breaks at primary level AND interior profile shows retail takeover simultaneously
- The whale's own partial alibi becomes publicly visible — they had to issue a statement, a disclosure, a rebuttal
- No waiting. No tiering. Full exit.

Stage D — Post-Exit Forensic Review

This is where the rubric gets smarter over time. Every completed trade feeds the system.

- Map which signals fired in correct sequence and which were false leads — rubric compounds accuracy through iteration

- Run Incomplete Distribution Check — did the actor fully exit, or does interior profile suggest interrupted distribution? If interrupted, log the node boundary for re-entry watch.
- Document which PR/media/analyst nodes were used in the Infrastructure Recycling Log. These get recycled. Next time this actor positions, the same fingerprint will appear earlier in the cycle — giving you longer lead time into entry.

Complete Logic at a Glance

```
// DETECTION
Phase 1 only (Managed Silence)           → Tier 1: 10-15%
Phase 1 only (Consensus Redundancy)       → Tier 1: 10% ceiling, watch only

Phase 1 + Phase 2 confirmed               → Add to Tier 2: 40-50% total
Phase 1 + Phase 2 ambiguous               → Hold Tier 1, do not build

All three phases compounded                → Complete to Tier 3: full position
Tier 3 deployed                           → Activate Stage B decay monitoring
immediately

// POSITION MANAGEMENT
Yellow exit signals                       → Scale back to Tier 2 size
Orange exit signals                       → Scale back to Tier 1 size
Red exit signals                           → Full exit. No tiering.

// LEARNING LOOP
Post-exit review                          → Infrastructure Recycling Log updated
Known actor confirmed                      → Forced Upgrade eligible next cycle
```

DIAGNOSTIC QUESTIONS — ONE PER PHASE

Phase 1 Is the information structure too clean?

Phase 2 Who benefits from this specific selection of managed content?

Phase 3 Where are we in the lifecycle, and how fast is it moving?

Phase 4 Do enough independent signals compound to justify action?

The whales think retail is their exit liquidity.
We read the silence they manufacture to move us.
